QUANTITATIVE GEOGRAPHY

GGM 201: RESEARCH METHODS FOR DISSERTATIONS

Christoph Stich
October 20, 2015

SLIDE 1

DEFINITION

SLIDE 2

Source: Oxford English Dictionary

Quantitative

- "That is, or may be, **measured** or assessed with respect to or on the basis of **quantity**; that may be expressed in terms of quantity; quantifiable."

Geography

- "The field of study concerned with the **physical features of the earth** and its atmosphere, and with **human activity** as it affects and is affected by these, including the **distribution** of populations and resources and political and economic activities; also as a subject of educational study or examination."

SLIDE 3

Fotheringham, Brunsdon, and Charlton (2000)

"One or more of the following activities:

- the analysis of numerical spatial data;
- the development of spatial theory;
- and the construction and testing of mathematical models of spatial processes"

Murray (2010)

"The collection of **methods** that are applied, or could/can be applied, by geographers and others to study **spatial** phenomena, issues and problems"

SLIDE 4

HISTORY

SLIDE 5

- As a practice, origin is very old and hard to pinpoint
- As a *movement*, 1950s/60s/70s → **Quantitative Revolution**
  - Focus on **quantification** and measurement
  - Adoption of the **scientific method**
  - Strong association with particular **methods**: statistics, modeling, mapping, mathematics, and hypothesis testing
  - Sprung out of a few epicenters (UW's "*space cadets*", Lund's T. Hagerstrand, also related to Isard's Regional Science)
  - One of the dominant strains in Physcial Geography after the 1950s - Pidwirny (2006)

SLIDE 6

- 1980s/90s → Cultural turn in Human Geography and other social sciences
- 1990s/00s → Cross-polination with and from other disciplines (economy, sociology, urban planning, public policy, …)

SLIDE 7

- **[My view]** Nowadays $\rightarrow$ Back in fashion? Big Data revolution, Internet of Things, Computational Social Sciences, ...
- Intricate relationship with the available tools at the time
    - Mainframes, satellites, machine learning, ...

SLIDE 8

QUANTITATIVE GEOGRAPHY TODAY

SLIDE 9

(Spatial) methods that can be/have been applied to *human* and *physical* geography problems and issues.

- Geographic Information Systems (GIS)
- Airborne sensing
- Statistics and exploratory spatial data analysis (ESDA)
- Mathematics and optimization
- Regional analysis
- Computer science and simulation

SLIDE 10

(Spatial) methods that can be/have been applied to *human* and *physical* geography problems and issues.

- Geographic Information Systems (GIS)
- Airborne sensing
- Statistics and exploratory spatial data analysis (ESDA)
- Mathematics and optimization
- Regional analysis
- Computer science and simulation

Let's walk through each of those with an example...

SLIDE 11

GEOGRAPHIC INFORMATION SYSTEMS (GIS)

"Collection of hardware, software, and associated procedures to support **spatial data**...

- acquisition,
- management,
- manipulation,
- analysis,
- and display"

SLIDE 12

Source: http://www.runkeeper.com

SLIDE 13
- **Acquisition**: collection of GPS traces (smartphone)
- **Management**: phone storage, transfer over server, orderly inserted into database
- **Manipulation**: transform traces (points) into an actual route (lines)
- **Analysis**: calculate distance, speed, climb, etc.
- **Display**: present information in an intuitive and efficient way

Other day-to-day examples of GIS?

Examples: Google Maps, Google Fit, National Rail website,...

"Geospatial sensing technologies that can be utilized for data collection and/or creation"

- Global position system (GPS)
- Photogrammetry
- Remote sensing

Talks about commonalities before going into detail

Commonalities:

- Not only geography but engineering, geodesy, and computer science
- Focus on **data collection**
- Importance of sensors
- Need for techniques to derive spatial information from raw measurements
    - Data doesn't just "talk" on its own

SLIDE 16

Systems (satellites, base stations and individual receivers) that enable (relative) accurate and fast measurments of **position** and **time**

How it works taken from Wikipedia: Each GPS satellite continually broadcasts a signal (carrier frequency with modulation) that includes:

A pseudorandom code (sequence of ones and zeros) that is known to the receiver. By time-aligning a receiver-generated version and the receiver-measured version of the code, the time of arrival (TOA) of a defined point in the code sequence, called an epoch, can be found in the receiver clock time scale A message that includes the time of transmission (TOT) of the code epoch (in GPS system time scale) and the satellite position at that time

Conceptually, the receiver measures the TOAs (according to its own clock) of four satellite signals. From the TOAs

and the TOTs, the receiver forms four time of flight (TOF) values, which are (given the speed of light)

approximately equivalent to receiver-satellite range differences. The receiver then computes its three-dimensional

position and clock deviation from the four TOFs.

How do we encounter this: Most likely you will have a receiver that tells you your position and time and you track something with this

- Capture, analysis, and interpretation of aerial photographs that represent spatial information
- Camera on balloons, planes, helicopters, drones, …

What it does Wikipedia: Photogrammetry is the science of making measurements from photographs, especially for recovering the exact positions of surface points. Moreover, it may be used to recover the motion pathways of designated reference points located on any moving object, on its components and in the immediately adjacent environment.Applications: Its applications include satellite tracking of the relative positioning alterations in all Earth environments (e.g. tectonic motions etc.), the research on the swimming of fish, of bird or insect flight, other relative motion processe

SLIDE 20

What do we see: Potential erosion, fish schools in coastal waters, landuse, ...

- Hardware, software and techniques for semi-automated spatial data collection
- Using aerial sensors to detect a propogated signal (e.g. electromagnetic radiation)
- Allows for collection of land cover, land uses, vegetation type, meterological data, ocean currents, desertification, …

What is it Wikipedia: Remote sensing is the acquisition of information about an object or phenomenon without making physical contact with the object and thus in contrast to on site observation. Remote sensing is a sub-field of geography. In modern usage, the term generally refers to the use of aerial sensor technologies to detect and classify objects on Earth (both on the surface, and in the atmosphere and oceans) by means of propagated signals (e.g. electromagnetic radiation). It may be split into active remote sensing (when a signal is first emitted from aircraft or satellites) or passive (e.g. sunlight) when information is merely recorded.

Algebra, geometry, calculus are at the core of much of Quantitative Geography.

Prominent Examples

- Spatial interaction models (trade, commuting, etc.)
- Spatial optimization (real world examples?)
- Network analysis (spatial networks: rivers, streets, the internet, …)

Interaction models are interested in the amount of stuff between nodesExamples: Say you have a store and want to maximize the catchment area of itUse graphs/networks to understand stuff

Ed Manley 2012
urbanmovements.co.uk
ESDA: **E**xploratory **S**patial **D**ata **A**nalysis

- One of the most extensive areas of Quantitative Geography
- Builds on non-spatial statistics, but incorporates **space** explicitly in its framework
- Main areas:
    - Surveying and sampling
    - Point pattern analysis
    - Spatial autocorrelation
    - Spatial statistics (regression, interpolation…)
    - Exploratory Spatial Data Analysis (ESDA) and interactive data exploration

Point pattern analysis (PPA) is the study of the spatial arrangements of points in (usually 2-dimensional) space. The simplest formulation is a set $X = x$ D where D, which can be called the 'study region,' is a subset of Rn, a n-dimensional Euclidean space. — A fundamental problem of PPA is inferring whether a given arrangement is merely random or the result of some process. The picture illustrates patterns of 256 points using four point processes. The clustered process results in all points having the same location. Popular models are those based on simple circles and ellipses, inter-point (and especially nearest neighbor) distances, quadrats, and intensity functions. Each model yields estimates (that can increase insights into the underlying real-world processes) as well as associated goodness-of-fit diagnostics.Spatial Autocorrelation:] A measure of the degree to which a set of spatial features and their associated data values tend to be clustered together in space (positive spatial autocorrelation) or dispersed (negative spatial autocorrelation).

\note{What did John Snow do in 1854 according to Wikipedia: By talking to local residents (with the help of Reverend Henry

- Techniques to support the understanding of urban and regional economies in a quantitative manner
- Obtain insights about:
    - Industry interactions
    - Impacts on sectors of the economy
    - Regional interdependencies
- Intimately connected to economic geography, **regional science** and economics

Murray: The category of regional analysis has reflected the need to understand urban and regional economies in a formal, quantitative manner. This is in terms of explaining what is currently taking place, but also why changes occurred and what changes are likely in the future. Many classical economics based methods have been relied upon for regional analysis, including the fundamentals of location theory (land rent models, cost minimization, central place hierarchies, and competition), input–output models, and computable general equilibrium models. These methods and others have been widely applied by geographers, but also extended in various ways — Regioonal comparison

COMPUTER SCIENCE AND SIMULATION*

- Mainly:
    - database design
    - algorithm design
    - simulation processes
- Traditionally *"the playground of non-geographers"*
- Recently, a much more reciprocal relationship
- Using computation to create **spatial** knowledge
    - Modelling human mobility,
- Increasing in relevance as datasets grow and your "average" problem becomes more computationally intensive

WHERE TO CONTINUE

If you like how all of this sounds, find more of it at GEES scattered in:

- [Y2] *Understanding neighborhood poverty*, by Dr. Lee
- [Y2] *Geomatics for Geographers* , by Dr. Chapman
- [Y2] *The Urban and Regional Economy* , by Dr. Tranos.
- [Y3] *Network Geographies*, by Dr. Tranos.
